December 2, 2024

**Note:** From this point onwards I will use tilde on top of a variable to denote that it is a vector.

1. Given the linear regression model in the form  $\tilde{y} = \mathbf{X}\tilde{\beta} + \tilde{\epsilon}$  where  $E[\tilde{\epsilon}] = 0$  and  $E[\tilde{\epsilon}\tilde{\epsilon}^T] = \sigma^2 I$ , and  $\tilde{\epsilon}$  is normally distributed, which implies that the least-squares estimator for  $\tilde{\beta}$

$$\tilde{\beta} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \tilde{y}$$

Where we require the matrix  $(\mathbf{X}^T \mathbf{X})$  to be invertible.

- a) Show that  $\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}$  is invertible, that is  $\det(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \neq 0$  when  $\lambda \neq 0$ , and  $\mathbf{I}$  is the identity matrix.

*Proof.* We know that  $\mathbf{X}^T \mathbf{X}$  is non-invertible, that is  $\det(\mathbf{X}^T \mathbf{X}) = 0$ , and  $a$  and  $d$  are non-negative.

$$\begin{aligned} \mathbf{X}^T \mathbf{X} + \lambda \mathbf{I} &= \begin{bmatrix} a & b \\ c & d \end{bmatrix} + \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} a + \lambda & b \\ c & d + \lambda \end{bmatrix} \end{aligned}$$

Using the formula of determinant of  $2 \times 2$  matrix, we have

$$\begin{aligned} \det(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) &= \det \left( \begin{bmatrix} a + \lambda & b \\ c & d + \lambda \end{bmatrix} \right) \\ &= (a + \lambda)(d + \lambda) - bc \\ &= ad + a\lambda + d\lambda + \lambda^2 - bc \\ &= ad + \lambda(a + d) + \lambda^2 - bc \end{aligned}$$

Given that  $\det(\mathbf{X}^T \mathbf{X}) = 0 \Rightarrow ad - bc = 0 \Leftrightarrow ad = bc$ .

$$\begin{aligned}\det(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) &= bc + \lambda(a + d) + \lambda^2 - bc \\ &= \lambda(a + d) + \lambda^2\end{aligned}$$

$$\because \lambda \neq 0 \Rightarrow \lambda^2 > 0$$

$$\begin{aligned}\because a, d \geq 0 &\Rightarrow a + d > 0 \\ &\Rightarrow \lambda(a + d) + \lambda^2 > 0\end{aligned}$$

$\therefore$  We have shown that  $\det(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \neq 0$  when  $\lambda \neq 0$ .  $\square$

b) Given the expression

$$(\tilde{y} - \mathbf{X}\tilde{\beta})^T(\tilde{y} - \mathbf{X}\tilde{\beta}) + \lambda\tilde{\beta}^T\tilde{\beta}$$

where  $\lambda > 0$

Let us expand the expression algebraically, using what we learned about minimizing  $(\tilde{y} - \mathbf{X}\tilde{\beta})^T(\tilde{y} - \mathbf{X}\tilde{\beta})$  to obtain the estimator  $\tilde{\beta}$  in terms of  $\mathbf{X}$ ,  $\tilde{y}$  and  $\lambda$ .

$$\begin{aligned}(\tilde{y} - \mathbf{X}\tilde{\beta})^T(\tilde{y} - \mathbf{X}\tilde{\beta}) &= (\tilde{y}^T - \tilde{\beta}^T \mathbf{X}^T)(\tilde{y} - \mathbf{X}\tilde{\beta}) \\ &= \tilde{y}^T \tilde{y} - \tilde{y}^T \mathbf{X}\tilde{\beta} - \tilde{\beta}^T \mathbf{X}^T \tilde{y} + \tilde{\beta}^T \mathbf{X}^T \mathbf{X} \tilde{\beta} \\ &= \tilde{y}^T \tilde{y} - 2\tilde{\beta}^T \mathbf{X}^T \tilde{y} + \tilde{\beta}^T \mathbf{X}^T \mathbf{X} \tilde{\beta} \\ (\tilde{y} - \mathbf{X}\tilde{\beta})^T(\tilde{y} - \mathbf{X}\tilde{\beta}) + \lambda\tilde{\beta}^T\tilde{\beta} &= \tilde{y}^T \tilde{y} - 2\tilde{\beta}^T \mathbf{X}^T \tilde{y} + \tilde{\beta}^T \mathbf{X}^T \mathbf{X} \tilde{\beta} + \lambda\tilde{\beta}^T\tilde{\beta} \\ &= \tilde{y}^T \tilde{y} - 2\tilde{\beta}^T \mathbf{X}^T \tilde{y} + \tilde{\beta}^T (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \tilde{\beta}\end{aligned}$$

Now let us minimize this expression by deriving it with respect to  $\tilde{\beta}$  and setting it to zero.

$$\begin{aligned}\frac{\partial}{\partial \tilde{\beta}}(\tilde{y}^T \tilde{y} + 2\tilde{\beta}^T \mathbf{X}^T \tilde{y} + \tilde{\beta}^T (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \tilde{\beta}) &= 0 \\ -2\mathbf{X}^T \tilde{y} + (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \tilde{\beta} &= 0 \\ \mathbf{X}^T \tilde{y} &= (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I}) \tilde{\beta} \\ \tilde{\beta} &= (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \tilde{y}\end{aligned}$$

$\therefore$  The estimator  $\tilde{\beta}$  in terms of  $\mathbf{X}$ ,  $\tilde{y}$  and  $\lambda$  is  $(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \tilde{y}$ .

c) Show that the estimator  $\tilde{\beta}$  is biased.

$$\begin{aligned}(\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \tilde{y} &= (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T (\mathbf{X} \beta + \epsilon) \\ &= (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \mathbf{X} \beta + (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \epsilon\end{aligned}$$

$$\text{Let } \mathbf{A} = (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \mathbf{X}$$

$$E[\tilde{\beta}] = E[A\beta] + (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T E[\epsilon]$$

$$E[\tilde{\beta}] = E[A\beta]$$

For  $\tilde{\beta}$  to be unbiased, we need  $E[\tilde{\beta}] = \beta \Leftrightarrow E[A\beta] = \beta \Leftrightarrow \mathbf{A} = \mathbf{I}$ , but we know that this is now true because  $\mathbf{A} = (\mathbf{X}^T \mathbf{X} + \lambda \mathbf{I})^{-1} \mathbf{X}^T \mathbf{X} \neq \mathbf{I}$ .

$\therefore$  The estimator  $\tilde{\beta}$  is biased.

2. Given that  $H_0 : \beta_2 = \beta_6 = 0$ , and  $H_0 : \beta_2 = \beta_6, \beta_3 = \beta_4$ .

a) A matrix  $T$  can represent the null hypothesis  $H_0 : \beta_2 = \beta_6 = 0$  as

$$T = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

b) A matrix  $T$  can represent the null hypothesis  $H_0 : \beta_2 = \beta_6, \beta_3 = \beta_4$  as

$$T = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & -1 & 0 & 0 \end{bmatrix}$$

Using the fact that  $\beta_2 = \beta_6 \Leftrightarrow \beta_2 - \beta_6 = 0$  and  $\beta_3 = \beta_4 \Leftrightarrow \beta_3 - \beta_4 = 0$ .

c) Under  $H_0 : \mathbf{T}\tilde{\beta} = 0$ , show that  $\text{Var}(\mathbf{T}\tilde{\beta}) = \sigma^2 \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T$ .

*Proof.*

$$\begin{aligned}\text{Var}(\mathbf{T}\tilde{\beta}) &= \text{Var}(\mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \tilde{\epsilon}) \\ &= \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \cdot \text{Var}(\tilde{\epsilon}) \cdot \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \\ &= \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \cdot \sigma^2 \mathbf{I} \cdot \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \\ &= \sigma^2 \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \\ &= \sigma^2 \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T\end{aligned}$$

$\therefore$  We have shown that  $\text{Var}(\mathbf{T}\tilde{\beta}) = \sigma^2 \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T$ . □

d) Under  $H_0 : \mathbf{T}\tilde{\beta} = 0$ , show that  $\mathbf{T}\tilde{\beta} = \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \tilde{\epsilon}$ .

*Proof.*

$$\begin{aligned}
\mathbf{T}\tilde{\beta} &= \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\tilde{y} \\
&= \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T(\mathbf{X}\beta + \epsilon) \\
&= \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{X}\beta + \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\epsilon \\
&= \mathbf{T}\beta + \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\epsilon \\
&= \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\epsilon
\end{aligned}$$

$\therefore$  We have shown that  $\mathbf{T}\tilde{\beta} = \mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\tilde{\epsilon}$ .  $\square$

e) Under  $H_0 : \mathbf{T}\tilde{\beta} = 0$ , show that  $\hat{\beta}^T\mathbf{T}^T\Sigma^{-1}\mathbf{T}\hat{\beta} \sim \chi_{(r)}^2$ , where  $\Sigma^{-1} = \text{Var}(\mathbf{T}\hat{\beta})^{-1}$ .

*Proof.* Recall that the  $\hat{\beta} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\tilde{y}$ , where  $\tilde{y} = \mathbf{X}\beta + \tilde{\epsilon}$ . The variance of  $\mathbf{T}\hat{\beta}$  is  $\text{Var}(\mathbf{T}\hat{\beta}) = \sigma^2\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T$ . Thus,

$$\begin{aligned}
\Sigma &= \sigma^2\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T \\
\Sigma^{-1} &= \frac{1}{\sigma^2}(\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T)^{-1}
\end{aligned}$$

Now we have

$$\begin{aligned}
\hat{\beta}^T\mathbf{T}^T\Sigma^{-1}\mathbf{T}\hat{\beta} &= \hat{\beta}^T\mathbf{T}^T\left(\frac{1}{\sigma^2}(\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T)^{-1}\right)\mathbf{T}\hat{\beta} \\
&= \frac{1}{\sigma^2}\hat{\beta}^T\mathbf{T}^T(\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T)^{-1}\mathbf{T}\hat{\beta}
\end{aligned}$$

Let us go back to our null hypothesis  $H_0 : \mathbf{T}\tilde{\beta} = 0$ . We know that the  $\hat{\beta}$  is normally distributed with mean 0 and covariance matrix  $\sigma^2(\mathbf{X}^T\mathbf{X})^{-1}$ , therefore so is  $\mathbf{T}\hat{\beta}$ . Then we have

$$\mathbf{T}\hat{\beta} \sim N(\mathbf{T}\beta, \sigma^2\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T)$$

Under  $H_0$  this becomes

$$\mathbf{T}\hat{\beta} \sim N(0, \sigma^2\mathbf{T}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{T}^T)$$

Now, let  $S$  be the statistic of our test, then

$$S = \frac{1}{\sigma^2} \hat{\beta}^T \mathbf{T}^T (\mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T)^{-1} \mathbf{T} \hat{\beta}$$

then  $S$  is definitely in a form of  $\chi^2$  distribution, we can show by letting

$$\mathbf{z} = \mathbf{T} \hat{\beta}$$

$$\mathbf{A} = \frac{1}{\sigma^2} (\mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T)^{-1}$$

and that implies,

$$S = \mathbf{z}^T \mathbf{A} \mathbf{z}$$

where  $\mathbf{z} \sim N(0, \sigma^2 \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T)$ , as shown above. The rank of  $\mathbf{T}$  is  $r = \mathbf{rank}(\mathbf{T})$ , which represents the number of linearly independent rows in  $\mathbf{T}$ , where it ultimately implies that the degrees of freedom of  $\chi^2$  distribution is  $r$ .

$\therefore$  We have shown that  $\hat{\beta}^T \mathbf{T}^T \Sigma^{-1} \mathbf{T} \hat{\beta} \sim \chi^2_{(\mathbf{rank}(\mathbf{T}))} = \chi^2_{(r)}$ .  $\square$

f) Show that

$$(\mathbf{I} - \mathbf{H})[\mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}] = 0$$

*Proof.* We know that  $\mathbf{H} = \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T$ , and  $\mathbf{C} = \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T$ . The term  $(\mathbf{I} - \mathbf{H})$  is the projection matrix that projects onto the orthogonal complement of the column space of  $\mathbf{X}$ . Thus we get:

$$\begin{aligned} (\mathbf{I} - \mathbf{H}) &= \mathbf{I} - \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \\ (\mathbf{I} - \mathbf{H})[\mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}] &= \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X} \\ &\quad - \mathbf{H}(\mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}) \end{aligned}$$

and since  $\mathbf{H}\mathbf{X} = \mathbf{X}$ , we have

$$\begin{aligned} &= \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X} \\ &\quad - \mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X} \\ &= 0 \end{aligned}$$

$\therefore$  We have shown that  $(\mathbf{I} - \mathbf{H})[\mathbf{X}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T}(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}] = 0$ .  $\square$

g) Under  $H_0 : \mathbf{T}\tilde{\beta} = 0$ , show that

$$F_0 = \frac{(\hat{\tilde{\beta}}^T \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T} \hat{\tilde{\beta}})/r}{MSE} \sim F_{(r, n-p)}$$

where MSE is computed for the full model (with p parameters)

From earlier proof, we know that  $\hat{\tilde{\beta}}^T \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T} \hat{\tilde{\beta}} \sim \chi_{(r)}^2$ . We also know that  $MSE = \frac{SSE}{n-p} \Leftrightarrow MSE \sim \chi_{(n-p)}^2$ . Then we have something like this

$$F_0 = \frac{(\hat{\tilde{\beta}}^T \mathbf{T}^T \mathbf{C}^{-1} \mathbf{T} \hat{\tilde{\beta}})/r}{SSE/(n-p)}$$

where we notice that this is a form of  $F$  distribution, where both numerator and denominator are some sort of  $\chi^2$  distribution now visually we can see that

$$= \frac{\sigma^2 \chi_r^2}{\sigma^2 \chi_{n-p}^2} = \frac{\chi_r^2}{\chi_{n-p}^2} \sim F_{(r, n-p)}$$

h) Find a matrix  $\mathbf{T}$  that represents some hypothesis:

$$H_\gamma : \beta_0 = \beta_1 = \beta_2 = \dots = \beta_k$$

*Proof.* Let us consider the hypothesis

$$H_\gamma : \beta_0 = \beta_1 = \beta_2 = \dots = \beta_k = \beta$$

(here we let  $\beta$  can represent a common value for all the parameters). We can represent this hypothesis as

$$\beta_0 - \beta = 0, \beta_1 - \beta = 0, \beta_2 - \beta = 0, \dots, \beta_k - \beta = 0$$

and our goal is to present this a matrix  $\mathbf{T}$  such that

$$\mathbf{T}\beta = 0$$

where  $\beta = [\beta_0, \beta_1, \dots, \beta_k]^T$ .

Now lets start constructing the matrix  $\mathbf{T}$ , with these constraints:

- i. We need the matrix  $\mathbf{T}$  to be the size of  $k_{\text{rows}} \times (k+1)_{\text{column}}$ , where  $k$  is the number of parameters and the  $+1$  is reserved for the intercept term.

- ii. The first column of  $\mathbf{T}$  represents constraints for  $\beta_0$ , the second column represents constraints for  $\beta_1$ , and so on.
- iii. Each row of  $\mathbf{T}$  represents the constraints of a parameter in some form  $\beta_i - \beta = 0$ . We can write this as  $\mathbf{T}\beta = \mathbf{c}$ .

$$\mathbf{T} = \begin{bmatrix} 1 & -1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & -1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & -1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{bmatrix}$$

then the  $\mathbf{T}\beta$  matrix will look like this

$$\mathbf{T}\beta = \begin{bmatrix} 1 & -1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & -1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & -1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \\ \beta_2 \\ \vdots \\ \beta_k \end{bmatrix} = \begin{bmatrix} \beta_0 - \beta_1 \\ \beta_1 - \beta_2 \\ \beta_2 - \beta_3 \\ \vdots \\ \beta_{k-1} - \beta_k \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

which implies that  $\mathbf{c} = 0 \Rightarrow \mathbf{T}\beta = 0$ .  $\therefore$  We have shown that the matrix  $\mathbf{T}$  that represents the hypothesis  $H_\gamma : \beta_0 = \beta_1 = \beta_2 = \cdots = \beta_k$  is  $\square$

3. Problem 3.25 on page 130, using “lm” function to answer the following questions. We are given that the linear regression model is

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \epsilon$$

- a.  $H_0 : \beta_1 = \beta_2 = \beta_3 = \beta_4 = \beta \Leftrightarrow \beta_1 - \beta = 0, \beta_2 - \beta = 0, \beta_3 - \beta = 0, \beta_4 - \beta = 0$ .

```
# Assuming that the data we are using is table.b1
# are the columns/predictors
# Load required library to use linearHypothesis()
library(car)
model = lm(y ~ x1 + x2 + x3 + x4, data = table.b1)

# testing the hypothesis
linear_hypothesis_test(model, "x1 = x2 = x3 = x4")
```

```

# function to perform hypothesis test using
# linearHypothesis()
linear_hypothesis_test <- function(model) {

# use matrix to specify the hypothesis and constraintss
# from the last proof we did in the previous question
hypothesis_matrix <- matrix(c(1, -1, 0, 0, 0,
                              0, 1, -1, 0, 0,
                              0, 0, 1, -1, 0,
                              0, 0, 0, 1, -1),
                             nrow = 4, ncol = 5, byrow = TRUE)

# specify the hypothesis (all coefficients equal to 0)
hypothesis_values <- c(0, 0, 0, 0)

# perform the linear hypothesis test
linear_hypothesis_result <- linearHypothesis(model,
                                              hypothesis_matrix,
                                              hypothesis_values)
return(linear_hypothesis_result)}

```

b.  $H_0 : \beta_1 = \beta_2, \beta_3 = \beta_4 \Leftrightarrow \beta_1 - \beta_2 = 0, \beta_3 - \beta_4 = 0$ .

# Let us use the same technique as above

```

linear_hypothesis_test(model, "x1 = x2, x3 = x4")

linear_hypothesis_test <- function(model) {

hypothesis_matrix <- matrix(c(0, 1, -1, 0, 0,
                              0, 0, 0, 1, -1),
                             nrow = 2, ncol = 5, byrow = TRUE)

(c) `t_stats <- summary_model_3.1$coefficients[, "t value"]`

#####

(Intercept)	x2	x7	x8
-0.228883	5.177090	2.198262	-3.771036

The conclusion we can draw about the roles the variables  $x_2$ ,  $x_7$ , and  $x_8$  play in predicting  $y$  is that  $x_2$  and  $x_7$  are significant predictors of  $y$  because their  $t$ -statistics are greater than 2 in absolute value, and their  $p$ -values are less than 0.05.  $x_8$  is **highly** significant predictor of

$y$  because its  $t$ -statistic is less than -2.

$\therefore$  We reject all null hypotheses that  $\beta_2 = 0$ ,  $\beta_7 = 0$ , and  $\beta_8 = 0$ .

```
(d) r_squared <- summary_model_3.1$r.squared
#####
[1] 0.7863069
adj_r_squared <- summary_model_3.1$adj.r.squared
#####
[1] 0.7595953
```

$\therefore$  The  $R^2$  value is 0.7863 and the adjusted  $R^2$  value is 0.7596.

```
(e) model_reduced <- lm(y ~ x2 + x8, data = table.b1)
summary(model_reduced)
#####
Call:
lm(formula = y ~ x2 + x8, data = table.b1)
```

Residuals:

Residual standard error: 1.832 on 25 degrees of freedom

Multiple R-squared: 0.7433, Adjusted R-squared: 0.7227

F-statistic: 36.19 on 2 and 25 DF, p-value: 4.152e-08

```
model_full <- model_3.1
```

```
# Get the residual sum of squares (RSS) for both models
```

```

RSS_full <- sum(residuals(model_full)^2)
RSS_reduced <- sum(residuals(model_reduced)^2)

# Get the number of parameters
# (coefficients) in the full and reduced models
p_full <- length(coef(model_full)) # including the intercept
p_reduced <- length(coef(model_reduced)) # including the intercept

# Get the degrees of freedom for the full model
df_full <- df.residual(model_full)

MSR_full <- (RSS_full - RSS_reduced) / (p_full - p_reduced)
MSR_reduced <- RSS_reduced / df_full

# Calculate the partial F-statistic
F_statistic <- MSR_full / MSR_reduced
F_statistic
#####
[1] 4.832354

```

Using the adjusted  $R^2$  value, we can see that the  $R^2$  value for the full model is 0.7863, and the  $R^2$  value for the reduced model is 0.7433. Which implies that the full model is better than the reduced model. The partial F-statistic is 4.832354, and we know that  $F = t^2$ , then we have  $t = 2.198262$ . This matches the t-statistic for  $x_7$  in the full model. This implies that the F-statistic and the t-statistic for  $\beta_7$  are directly related.

5. Problem 3.2 on page 125. Using the results of Problem 3.1, we can show numerically that the square of the simple correlation coefficient between the observed values  $y_i$  and the fitted values  $\hat{y}_i$  is equal to the  $R^2$ . Where  $R^2$  is the coefficient of determination, and the formula is as follows

$$R^2 = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SST}}$$

where SSR is the sum of squares of the regression, SST is the total sum of squares, and SSE is the sum of squares of the error. The correlation

coefficient  $r$  between  $y_i$  and  $\hat{y}_i$  is given by

$$r = \frac{\text{Cov}(y, \hat{y})}{\sqrt{\text{Var}(y)\text{Var}(\hat{y})}}$$

and the claim is that  $r^2 = R^2$ .

```
model <- lm(y ~ x2 + x7 + x8, data = table.b1)

R_squared <- summary(model)$r.squared

y_fitted <- fitted(model)
y_observed <- table.b1$y
r <- cor(y_observed, y_fitted)
r_squared <- r^2
cat("R squared (from model): ", R_squared, "\n")
cat("R squared (from correlation): ", r_squared, "\n")
#####
R squared (from model):  0.7863069
R squared (from correlation):  0.7863069
```

$\therefore$  We have shown that the square of the simple correlation coefficient  $r^2$  between the observed values  $y_i$  and the fitted values  $\hat{y}_i$  is equal to the  $R^2$ .

6. Problem 3.3 on page 125. Referring to Problem 3.1,

- a. Find a 95% confidence interval for  $\beta_2$ . Let CI be the confidence interval. Then we need to find,

$$\text{CI} = \hat{\beta}_2 \pm t_{(0.5, n-p)} \times \text{SE}(\hat{\beta}_2)$$

where  $\hat{\beta}_2$  is the estimate of  $\beta_2$ ,  $t_{\alpha/2, n-p}$  is the critical value of the  $t$ -distribution

```
coefficients <- summary(model)$coefficients
beta_2 <- coefficients["x2", "Estimate"]
SE_beta_2 <- coefficients["x2", "Std. Error"]
```

```
df <- df.residual(model)

t_crit <- qt(0.975, df)

CI_beta_2 <- c(beta_2 - t_crit * SE_beta_2,
               beta_2 + t_crit * SE_beta_2)
#####
[1] 0.002163664 0.005032477
```

$\therefore$  The 95% confidence interval for  $\beta_2$  is (0.002163664, 0.005032477).

- b. Find a 95% confidence interval on the mean number of games won by a team when  $x_2 = 2300$ ,  $x_7 = 56.0$ , and  $x_8 = 2100$

```
# new obs
new_obs <- data.frame(x2 = 2300, x7 = 56.0, x8 = 2100)

# predict
y_hat <- predict(model, new_obs)

SE_y_hat <- predict(model, new_obs, se.fit = TRUE)$se.fit

CI_y_hat <- c(y_hat - t_crit * SE_y_hat,
             y_hat + t_crit * SE_y_hat)
print(CI_y_hat)
#####
1          1
6.436203 7.996645
```

$\therefore$  The 95% confidence interval for when  $x_2 = 2300$ ,  $x_7 = 56.0$ , and  $x_8 = 2100$  is (6.436203, 7.996645).

7. Problem 3.4 on page 126. Remodling table.b1 using,  $x_7$  and  $x_8$  as the predictors, and  $y$  as the response.

- a. Test for significane of regression

```
new_model <- lm(y ~ x7 + x8, data = table.b1)
#####
```

```

Call:
lm(formula = y ~ x7 + x8, data = table.b1)

Residuals:
    Min       1Q   Median       3Q      Max
-3.7985 -1.5166 -0.5792  1.9927  4.5248

Coefficients:
              Estimate Std. Error t value Pr(>|t|)
(Intercept) 17.944319   9.862484   1.819  0.08084 .
x7           0.048371   0.119219   0.406  0.68839
x8          -0.006537   0.001758  -3.719  0.00102 **
---
Signif. codes:  0 '***' 0.001
                '***' 0.01 '***' 0.05 '***' 0.1 '***' 1

Residual standard error: 2.432 on 25 degrees of freedom
Multiple R-squared:  0.5477, Adjusted R-squared:  0.5115
F-statistic: 15.13 on 2 and 25 DF,
p-value: 4.935e-05

```

$\therefore$  The regression is **highly** significant because the p-value  $4.935 \times 10^{-5} < 0.05$

b. Calculate the  $R^2$  and adjusted  $R^2$  values

```

R_squared <- summary(new_model)$r.squared
adj_R_squared <- summary(new_model)$adj.r.squared
cat("R squared: ", R_squared, "\n")
cat("Adjusted R squared: ", adj_R_squared, "\n")
#####
R squared:  0.547682
Adjusted R squared:  0.5114655

```

$\therefore$  These  $R^2$  and adjusted  $R^2$  values computed compared to 3.1 are lower, signifying that the model did not fit as well as the previous model.

- c. Calculate 95% CI on  $\beta_7$  and find 95% CI on the mean number of games won by a team when  $x_7 = 56.0$  and  $x_8 = 2100$ .

```

coefficients <- summary(new_model)$coefficients
beta_7 <- coefficients["x7", "Estimate"]
SE_beta_7 <- coefficients["x7", "Std. Error"]

df <- df.residual(new_model)

t_crit <- qt(0.975, df)

CI_beta_7 <- c(beta_7 - t_crit * SE_beta_7,
               beta_7 + t_crit * SE_beta_7)
print(CI_beta_7)
#####
[1] -0.1971643  0.2939060

# new obs
new_obs <- data.frame(x7 = 56.0, x8 = 2100)

# predict
y_hat <- predict(new_model, new_obs)

SE_y_hat <- predict(new_model,
                    new_obs, se.fit = TRUE)$se.fit

CI_y_hat <- c(y_hat - t_crit * SE_y_hat,
              y_hat + t_crit * SE_y_hat)
print(CI_y_hat)
#####
1          1
5.828643 8.023842

```

$\therefore$  The 95% confidence interval for  $\beta_7$  is  $(-0.1971643, 0.2939060)$ , and the 95% confidence interval for when  $x_7 = 56.0$  and  $x_8 = 2100$  is  $(5.828643, 8.023842)$ .

- d. Conclusions we can draw from this problem of omitting an important regressor  $x_2$  from the model, is that the model performed significantly

worst, as the  $R^2$  and adjusted  $R^2$  values are lower than the previous model and the confidence intervals are wider, which means that the estimates are less precise.

8. Bonus Problem

- (a) Show that  $SSR(\tilde{\beta}_2|\tilde{\beta}_1) = \tilde{\epsilon}^T(\mathbf{H} - \mathbf{H}_1)\tilde{\epsilon}$ , if  $H_0 : \beta_2 = 0$  is true.
- (b) Show that  $\frac{SSR(\tilde{\beta}_2|\tilde{\beta}_1)}{\sigma^2} \sim \chi^2_{(r)}$ .
- (c) Show that  $\frac{SSR(\tilde{\beta}_2|\tilde{\beta}_1)}{MSE} \sim F(r, n - p)$ .

End of Assignment 3.
